

Series-shunt bootstrapping preamplifier circuit for free space optics

Abstract

The signal level in an optical wireless receiver is weakest at the front-end due to the photo detector capacitance and appropriate design should be done to improve the receiver performance [1]. The optimum receiver performance can be achieved depends on the devices and design techniques used. Thus, this paper examines some of the issues involved in the design of front-end optical wireless receiver. Series-shunt bootstrap was investigated as the technique for mitigating the effects of the large capacitances associated with the photo detector. Optical wireless link or free space optics (FSO) require a large aperture and thus, the receiver is required to have a large detection area, which produces a high input capacitance and consequently reduced the bandwidth [1,2]. In order to maximize the bandwidth, we need to reduce C_{in} which is the summation of photodiode capacitance, C_d and amplifier input capacitance, C_s . On the other hand, it is necessary to reduce R_L but the thermal noise element will increase when the load resistor is reduced.
